INTERPRETATION :

Summary of HBsAg

HBV infection produces an array of unique antigens and antibodies which follow distinct and individual serological patterns. By monitoring these markers, it is possible not only to diagnose infection, but also to determine the stage of the disease and probable prognosis. HBsAg is the first marker to appear following infection, and is the best indirect indicator of potentially infectious sera. False positive HBsAg results can be obtained due to the presence of other antigens or elevated levels of RF factor. This can occur in $< 1\%$ of sample tested.
